

Deployment Is Not Adoption.

Adoption Is Not Value.

A four-page companion for separating availability, repeat use and attributable business outcome before a scale decision.

availability

trusted use

net value

Scale only after all three questions have evidence.

Three gates. Three different decisions.

Do not collapse deployment, adoption and value into one success metric.

Deployment

Can it run reliably?

available to the target users

permissions and run path work

exceptions are visible

Does not prove trust or value

Adoption

Does real work complete through it?

repeat use in the intended path

exceptions and overrides understood

workarounds are shrinking

Does not prove net value

Value

Is the outcome better enough?

baseline and comparison group

quality / time / risk movement

support and control cost included

Does not prove causality alone

Portfolio decision after the gates: SCALE · REPAIR · HOLD · STOP

Adoption often fails at trust, not training.

A procurement-analytics field note: users still export because touchable data feels safer.

What users said

They used the platform, but still preferred to download raw data into Excel, create pivots, move fields, and “touch” the numbers before trusting an analysis.

**Not a training problem by itself.
A trust and operating-context problem.**

Make the evidence inspectable

Users must see rules, missing data, exceptions and path from input to output.

Measure trusted completion

Usage is weak evidence if users finish the work somewhere else.

Push carefully

Leadership can start adoption, but trust sustains it.

Read the export as a signal: users want an inspectable path from input to output.

The executive output is a decision, not a dashboard.

Use the evidence gates to choose what deserves more investment.

Scale

stable · adopted · value-evidenced

Repair

use-case sound, trust/ops/value gaps

Hold

useful, but evidence incomplete

Stop

problem weak or support burden too high

Three questions before funding the next phase

- How much eligible work completes through the intended trusted path?
- What work disappeared, and what moved to reviewers, support or exception handling?
- Which benefits are observed and attributable, which are modelled, and which can change an operating decision?
